DETAILS OF EXACT LOW PRANDTL NUMBER BOUNDARY-LAYER

SOLUTIONS FOR FORCED AND FOR FREE CONVECTION

By E. M. Sparrow and J. L. Gregg

SUMMARY

↓ A detailed report is given of exact (numerical) solutions of the laminar-boundary-layer equations for the Prandtl number range appropriate to liquid metals (0.003 to 0.03). Consideration is given to the following situations: (1) forced convection over a flat plate for the conditions of uniform wall temperature and uniform wall heat flux, and (2) free convection over an isothermal vertical plate. Tabulations of the new solutions are given in detail. Results are presented for the heat-transfer and shear-stress characteristics; temperature and velocity distributions are also shown. The heat-transfer results are correlated in terms of dimensionless parameters that vary only slightly over the entire liquid-metal range. Previous analytical and experimental work on low Prandtl number boundary layers is surveyed and compared with the new exact solutions.

INTRODUCTION

Interest in the use of liquid metals as heat-transfer media has been stimulated by nuclear-reactor applications. Because of their high thermal conductivity, liquid metals are characterized by Prandtl numbers that lie far below those of conventional media such as gases and ordinary liquids. As a consequence, the large body of heat-transfer information available for conventional fluids cannot be used directly for liquid metals. This circumstance has provided the motivation for heat-transfer research in the low Prandtl number range.

It is the purpose of this report to present exact (numerical) solutions of the laminar-boundary-layer equations for the Prandtl number range appropriate to liquid metals (0.003 to 0.03). Consideration is given to both forced-convection and free-convection boundary layers. For forced convection, solutions are obtained for flow over a flat plate for both the uniform-wall-temperature and uniform-heat-flux cases. The free-convection solutions are for the isothermal vertical plate.

Previous investigations of the low Prandtl number heat-transfer characteristics of the forced-convection boundary layer have been carried out with approximate analytical techniques. The method of reference 1 is based on the fact that the velocity boundary layer is much thinner than the thermal boundary layer when the Prandtl number is small. Thus, in the outer part of the thermal boundary layer, the velocity was taken from the potential-flow solution; and only in the inner part was an approximate correction made for the nonuniformity of the velocity distribution. Another approximate solution is given in reference 2, where the well-known Kármán-Pohlhausen procedure is used. The results of references 1 and 2 will be compared with those from the exact solutions obtained herein.

For the free-convection boundary layer on an isothermal vertical plate, isolated numerical solutions for the low Prandtl number range have been reported in reference 3 ( $\text{Pr} = 0.01$ ) and reference 4 ( $\text{Pr} = 0.03$ ). The Kármán-Pohlhausen approximation method has been applied to the problem in references 5 and 6. A somewhat different approximation procedure is used in reference 7, where polynomials are also used but the coefficients of the polynomial are found by satisfying the boundary-layer equations at selected points. Heat-transfer results are given for  $\text{Pr} = 0.03$ . An experiment utilizing liquid mercury as working fluid ( $\text{Pr} = 0.025$ ) is also reported in reference 7. Again, comparisons will be made between the previous work and the new exact solutions.

An abbreviated presentation of some of the heat-transfer results corresponding to the new exact solutions\* has been made in reference 8 (forced convection) and reference 9 (free convection). Other aspects of these solutions could not be given there because of space limitations. In the present report, the complete details are presented, including among other information the temperature and velocity distributions and full tabulation of the solutions. These tabulations and curves should prove useful to future investigators of low Prandtl number boundary layers; for example, as a source of information from which special characteristics of the boundary layer may be computed (e.g., thickness parameters), or as input data for the solution of related problems, or as a standard against which to compare experimentally determined temperature and velocity profiles. In addition, the present report brings together the existing work on low Prandtl number boundary layers and attempts to provide an integrated picture of what is currently known. Finally, the forced-convection solutions for  $\text{Pr} = 0.003$ , not available at the time reference 8 was published, are also given here. The forced-convection and free-convection boundary layers are treated separately.

---

\*After a preliminary printing of this MEMORANDUM, the authors found that heat-transfer results corresponding to exact solutions for the forced-convection, uniform-wall-temperature case had also been published in reference 13.

## SYMBOLS

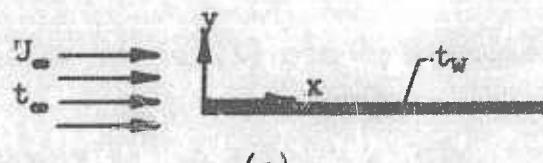

|                 |  |
|-----------------|--|
| $c_p$           | specific heat at constant pressure   |
| $c_f$           | friction factor, $2\tau/\rho U_\infty^2$   |
| $c_f^*$         | modified friction factor for free convection, $\tau/\rho \left(\frac{v}{x}\right)^2$ |
| F               | Blasius velocity function for forced convection, eq. (6b)                            |
| f               | velocity function for free convection, eq. (26b)                                     |

| $Re_L$     | Reynolds number, $U_\infty l / \nu$  |
| $Re_x$     | Reynolds number, $U_\infty x / \nu$  |
| St         | Stanton number, $Nu / RePr$  |
| t          | static temperature   |
| $t_w$      | wall temperature   |
| $t_\infty$ | ambient temperature  |
| $U_\infty$ | free-stream velocity   |
| u          | velocity component in x-direction  |
| v          | velocity component in y-direction  |
| x          | coordinate measuring distance along plate from leading edge  |
| y          | coordinate measuring distance normal to plate  |
| $\alpha$   | thermal diffusivity, $k/\rho c_p$  |
| $\beta$    | coefficient of thermal expansion, $- \frac{1}{\rho} \left( \frac{\partial \rho}{\partial t} \right)_p$ |
| $\zeta$    | free-convection similarity variable, eq. (26a)   |
| $\eta$     | forced-convection similarity variable, eq. (6a)  |
| $\theta$   | dimensionless temperature, $(t - t_\infty) / (t_w - t_\infty)$   |
| $\mu$      | absolute viscosity   |
| $\nu$      | kinematic viscosity  |
| $\rho$     | density  |
| $\tau$     | shear stress at plate surface  |
| $\psi$     | stream function  |

## FORCED-CONVECTION BOUNDARY-LAYER SOLUTIONS

## Brief Review of Theory

First, attention is focused on the flow and heat transfer about a flat plate aligned parallel to a uniform free stream, as pictured in the following sketch:

(a)

The problem is governed by the basic conservation laws: mass, momentum, and energy. The boundary-layer form of these equations for laminar, constant-property, nondissipative flow over a flat plate is

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \quad (1)$$

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2} \quad (2)$$

$$u \frac{\partial t}{\partial x} + v \frac{\partial t}{\partial y} = \alpha \frac{\partial^2 t}{\partial y^2} \quad (3)$$

The viscous dissipation term has been deleted from the energy equation (3) because of its negligible effect on the heat transfer to low Prandtl number fluids (ref. 10).

As a consequence of the constant-property assumption, the velocity problem for the forced-convection flow can be solved without recourse to the temperature. Turning first to the velocity, the statement of the problem is completed by giving the boundary conditions

$$\left. \begin{array}{l} u = 0 \\ y = 0 \\ v = 0 \end{array} \right\} \quad u \rightarrow U_{\infty} \quad y \rightarrow \infty \quad (4)$$

The conditions that  $u = v = 0$  at the wall ( $y = 0$ ) arise respectively from the requirements of no slip and impermeability of the wall to mass. The mathematical problem represented by equations (1) and (2) with the boundary conditions (4) was first solved by Blasius in 1908. Equation (1) is immediately satisfied by the usual stream function  $\psi$ :

$$u = \frac{\partial \psi}{\partial y}, \quad v = -\frac{\partial \psi}{\partial x} \quad (5)$$

For equation (2), Blasius introduced his famous similarity variable  $\eta$ :

$$\eta = \frac{y}{2x} \sqrt{\frac{U_\infty x}{v}} \quad (6a)$$

and a dimensionless stream function  $F$ , given by

$$F = \psi / \sqrt{v U_\infty x} \quad (6b)$$

This transformation reduces equation (2) to the well-known Blasius equation,

$$F''' + FF'' = 0, \quad F(0) = F'(0) = 0, \quad F' \rightarrow 2 \text{ as } \eta \rightarrow \infty \quad (7)$$

where the boundary conditions have been evaluated from (4), and the primes denote differentiation with respect to  $\eta$ . Although a solution of equation (7) was given by Blasius, it was necessary to re-solve to greater accuracy for the purposes of this investigation.

For the isothermal wall, the energy equation (3) was first solved by E. Pohlhausen. Using Blasius' similarity assumption (6a) together with a dimensionless temperature

$$\theta(\eta) = \frac{t - t_\infty}{t_w - t_\infty} \quad (8)$$

he reduced equation (3) to the form

$$\theta'' + (\text{Pr})F\theta' = 0 \quad (9a)$$

where  $\text{Pr}$  represents the Prandtl number. The physical boundary conditions that  $t = t_w = \text{const}$  at  $y = 0$  and  $t \rightarrow t_\infty$  as  $y \rightarrow \infty$  are transformed to

$$\theta(0) = 1, \quad \theta \rightarrow 0 \text{ as } \eta \rightarrow \infty \quad (9b)$$

The solution of the transformed energy equation (9a) depends upon the prior specification of the Prandtl number. Previous investigators have restricted themselves to  $\text{Pr} \geq 0.6$ .

For the situation of uniform wall heat flux, the surface temperature will not be constant but, as will be shown later, will vary along the plate according to the law

$$t_w - t_\infty = Ax^{1/2} \quad (10)$$

where  $A$  is a constant to be determined from the analysis. Taking cognizance of this variation in  $t_w$ , the energy equation (3) can be reduced to an ordinary differential equation by using the same transformation variables  $\eta$ ,  $F$ , and  $\theta$  as before. The result of the transformation is

$$\theta'' + \text{Pr}(F\theta' - F'\theta) = 0 \quad (11a)$$

The physical boundary conditions that  $t = t_w$  at  $y = 0$  and  $\theta \rightarrow 0$  as  $y \rightarrow \infty$  become

$$\theta(0) = 1, \quad \theta \rightarrow 0 \text{ as } \eta \rightarrow \infty \quad (11b)$$

Previous solutions of equation (11a) have been confined to the range  $\text{Pr} \geq 0.7$ .

#### Solutions and Results

Solutions. - The governing equations (9) and (11) for the uniform-wall-temperature and uniform-heat-flux problems have been solved numerically for Prandtl numbers of 0.03, 0.01, 0.006, and 0.003 utilizing an IBM 650 electronic computer. The numerical technique, described in detail in reference 11, is a forward integration procedure that requires both the function and its derivative to be specified at the starting point of the calculation for a second-order equation. In terms of the present problem, it is necessary that the pair  $(\theta(0), \theta'(0))$  be given. As is seen from the boundary conditions (9b) or (11b), the derivative  $\theta'(0)$  is not known. Therefore, the computational problem reduces to a systematic search for the appropriate values of the derivative that lead to solutions of equations (9) and (11) satisfying the condition  $\theta \rightarrow 0$  as  $\eta \rightarrow \infty$ . In this way, the two-point boundary-value problem is rephrased as an initial-value problem.

The values of  $\theta'(0)$  that correspond to solutions of equations (9) and (11) are listed in table I:

TABLE I. - FORCED-CONVECTION

#### TEMPERATURE DERIVATIVES

| Pr   | $[-\theta'(0)]_{UWT}$ | $[-\theta'(0)]_{UHF}$ |
|------|-----------------------|-----------------------|
| 0.03 | 0.16878               | 0.24838               |
| .01  | .10318                | .15512                |
| .006 | .081449               | .12345                |
| .003 | .058742               | .089850               |

In addition to their computational importance, these magnitudes are directly related to the heat-transfer characteristics of the flow (as will be shown later) and are therefore of immediate practical interest. In the table, the subscripts UWT and UHF are used to denote uniform wall temperature and uniform heat flux.

The low Prandtl number solutions of equations (9) and (11) are presented in detail in tables II and III (see pp. 23 to 30). For each of the eight cases considered, the dimensionless temperature  $\theta$  and its derivative  $\theta'$  are tabulated<sup>1</sup> as a function of the independent variable  $\eta$ . These tabulations should prove useful to future investigators of low Prandtl number boundary layers.

Temperature and velocity profiles. - Some insight into the thermal and flow fields may be obtained by inspection of the temperature and velocity distributions across the boundary layer. These are plotted in figure 1(a) for the case of uniform wall temperature and in figure 1(b) for the uniform-heat-flux case. From both of these figures, two important characteristics are immediately evident: First, that the thermal boundary layer is significantly thicker than the velocity boundary layer;<sup>2</sup> and secondly, that this disparity in thickness increases with decreasing Prandtl number. This suggests that the velocity boundary layer will play an ever-diminishing role in the heat-transfer process as the Prandtl number becomes smaller. Thus, for fluids with very small Prandtl numbers, the heat transfer will be essentially the same as that convected by an inviscid fluid. The solution for the heat transfer to an inviscid flow (ref. 1) thus appears as a limiting case.

Comparison of figures 1(a) and (b) indicates that, for a fixed Prandtl number, the thermal boundary layer corresponding to uniform wall temperature is somewhat thicker than that for uniform heat flux.<sup>3</sup> It would thus be expected that, at a given Prandtl number, the uniform-wall-temperature situation will be closer to its inviscid limit than the uniform-heat-flux case will be to its limit.

---

<sup>1</sup>The tables represent a condensation of the actual machine computations, which were run at a step size  $\Delta\eta$  of 0.025 and eight figures.

<sup>2</sup>This is in contrast to gases or ordinary liquids, where the thermal-boundary-layer thickness is either the same order as or less than the velocity-boundary-layer thickness.

<sup>3</sup>It may be interesting to note that, for the wall-temperature variation  $t_w - t_\infty = Ax^n$ , of which equation (10) is a special case, the thermal boundary layer is thicker as  $n$  decreases.

Heat-transfer results. - The local rate of heat transfer from the surface to the fluid may be calculated using Fourier's law:

$$q = -k \left( \frac{\partial t}{\partial y} \right)_{y=0} \quad (12)$$

In terms of the variables of the analysis as given by equations (6a) and (8), the expression for  $q$  becomes

$$q = -\frac{k}{2} (t_w - t_\infty) \sqrt{\frac{U_\infty}{v_x}} \theta'(0) \quad (12a)$$

where  $\theta'(0)$  is a function of Prandtl number found from solutions of equations (9) and (11) and listed in table I. Clearly, for  $q$  to be independent of  $x$ , the temperature difference  $t_w - t_\infty$  must vary as  $x^{1/2}$ , as prescribed by equation (10).

It is customary to phrase the local heat-transfer results in terms of a heat-transfer coefficient and a Nusselt number defined as follows:

$$h = \frac{q}{t_w - t_\infty}, \quad Nu_x = \frac{hx}{k} \quad (13)$$

Utilizing these definitions, equation (12a) becomes

$$\frac{Nu_x}{Re_x^{1/2}} = \frac{-\theta'(0)}{2} \quad (14)$$

where  $Re_x$  represents the Reynolds number. From equation (14), it is seen that the values of  $\theta'(0)$  appearing in table I are directly applicable to the Nusselt-Reynolds relation.

For low Prandtl numbers, it is fruitful to rephrase equation (14) as<sup>4</sup>

$$\frac{Nu_x}{(Re_x Pr)^{1/2}} = \frac{-\theta'(0)}{2Pr^{1/2}} \quad (14a)$$

---

<sup>4</sup>This step is suggested by the fact that  $Nu/(Re_x Pr)^{1/2}$  is a constant for the inviscid flow.

where the product  $Re_x Pr$  is sometimes referred to as the Peclet number. The dimensionless heat-transfer results in the form given by equation (14a) are listed in table IV:

TABLE IV. - FORCED-CONVECTION

## HEAT-TRANSFER RESULTS

| Pr                 | $Nu_x / (Re_x Pr)^{1/2}$ |        |
|--------------------|--------------------------|--------|
|                    | UWT                      | UHF    |
| 0.03               | 0.4872                   | 0.7170 |
| .01                | .5159                    | .7756  |
| .006               | .5257                    | .7969  |
| .003               | .5362                    | .8202  |
| Pr $\rightarrow 0$ |                          |        |
| Inviscid           | 0.564                    | 0.886  |

There are also included in the table entries corresponding to the limiting case of inviscid flow over a flat plate, for which  $Nu_x / (Re_x Pr)^{1/2}$  is a constant (ref. 1).

From table IV it is immediately seen that the variation of the group  $Nu_x / (Re_x Pr)^{1/2}$  is rather small over the entire liquid-metal range, being of the order of 10 percent. A more careful inspection of the table reveals that the variation is somewhat greater among the uniform-heat-flux results than it is among the uniform-wall-temperature results. This occurrence may be understood by recalling that the thermal boundary layer is thinner for the uniform-heat-flux problem and hence is more aware of the presence of the velocity boundary layer. The heat-transfer results based on the boundary-layer solutions smoothly approach that of the inviscid flow, the uniform-wall-temperature situation always being a little closer to its limiting value than the uniform-heat-flux case is to its limit. The heat-transfer results appearing in table IV are also plotted in figure 2.

The utility of the Reynolds-Prandtl product as a correlation parameter for low Prandtl number, laminar-boundary-layer heat transfer is noteworthy; especially since it has also served successfully in correlating turbulent-heat-transfer results for liquid-metal flow in tubes.

In the case of uniform wall temperature, it is often useful to know the over-all heat transfer  $Q$  from the entire surface. For a unit width of plate,  $Q$  is found from

$$Q = \int_0^L q dx \quad (15)$$

The integration may be carried out utilizing the local heat transfer  $q$  as given by equation (12a). The final result may be cast in a dimensionless form by defining an average heat-transfer coefficient and Nusselt number,

$$\bar{h} = \frac{Q}{L(t_w - t_\infty)}, \quad \overline{\text{Nu}}_L = \frac{\bar{h}L}{k} \quad (16)$$

from which it follows that

$$\frac{\overline{\text{Nu}}_L}{\text{Re}_L^{1/2}} = -\theta'(0) \quad (17a)$$

or

$$\frac{\overline{\text{Nu}}_L}{(\text{Re}_L \text{Pr})^{1/2}} = \frac{-\theta'(0)}{\text{Pr}^{1/2}} \quad (17b)$$

The numerical values of the dimensionless heat-transfer group given by equation (17b) are simply twice those listed in table IV.

Comparison with previous investigations. - As has been noted in the INTRODUCTION, approximate solutions for the low Prandtl number, forced-convection boundary layer have been given in references 1 and 2. The heat-transfer results corresponding to these solutions may be expressed as follows:

(a) Morgan's velocity approximation (ref. 1):

$$\left[ \frac{\text{Nu}_x}{(\text{Re}_x \text{Pr})^{1/2}} \right]_{\text{UWT}} = 0.564 - 0.547 \text{ Pr}^{1/2} \quad (18a)$$

$$\left[ \frac{\text{Nu}_x}{(\text{Re}_x \text{Pr})^{1/2}} \right]_{\text{UHF}} = 0.886 - 0.491 \text{ Pr}^{1/2} \quad (18b)$$

(b) Kármán-Pohlhausen method (ref. 2):

$$\left[ \frac{Nu_x}{(Re_x Pr)^{1/2}} \right]_{UWT} = \frac{0.529}{(1 + 0.82 Pr^{1/2})} \quad (19a)$$

$$\left[ \frac{Nu_x}{(Re_x Pr)^{1/2}} \right]_{UHF} = \frac{0.816}{(1 + 1.064 Pr^{1/2})} \quad (19b)$$

To facilitate comparison with the exact boundary-layer solutions, these equations have been plotted in figure 2.

Turning first to the uniform-wall-temperature situation as shown in figure 2(a), it is seen that Morgan's results tend to approach the exact solution more and more closely as the Prandtl number decreases. This behavior is to be expected from the structure of Morgan's solution. The greatest deviation, at  $Pr = 0.03$ , is only 4 percent. The Kármán-Pohlhausen results fall about 5 percent below the exact solution over the entire range.

Now, passing to the uniform-heat-flux case (fig. 3(b)), it may be noted that, while Morgan's results still tend to approach the exact solution with decreasing Prandtl number, the deviations are larger and of different sign than those of figure 2(a). Because of the thinner thermal boundary associated with the uniform-heat-flux problem, this somewhat less successful performance of Morgan's method is not surprising. The results from the Kármán-Pohlhausen method continue to fall about 5 percent below those of the exact solution.

Modified Reynolds analogy. - It is of interest to determine the form of Reynolds analogy appropriate to low Prandtl number, forced-convection boundary-layer flows. It is to be recalled that Reynolds analogy compares the friction and heat-transfer characteristics of the flow.

As a prelude, it may be recalled that the friction factor  $c_f$  for flow over a flat plate is given by

$$c_f = \frac{\tau}{(\rho U_\infty^2 / 2)} = \frac{0.664}{Re_x^{1/2}} \quad (20)$$

Next, the Stanton number is introduced by its definition

$$St = \frac{Nu_x}{Re_x Pr} \quad (21)$$

Then, taking the ratio of (21) to (20), there is obtained

$$\frac{St}{c_f} = \frac{1}{0.664} Pr^{1/2} \left[ \frac{Nu_x}{(Re_x Pr)^{1/2}} \right] \quad (22)$$

As has been pointed out in connection with table IV, the bracketed factor varies only moderately over the liquid-metal range; therefore, to achieve a concise result here, an average value will be used. With this approximation, equation (22) becomes

$$\left( \frac{St}{c_f} \right)_{UWT} = \frac{0.770}{Pr^{1/2}} \quad (23a)$$

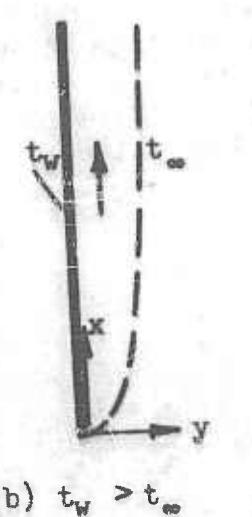

$$\left( \frac{St}{c_f} \right)_{UHF} = \frac{1.15}{Pr^{1/2}} \quad (23b)$$

It is important to observe that these relations deviate from the form of Reynolds analogy used for ordinary fluids, the difference being in the appearance of  $Pr^{1/2}$  rather than in the more customary  $Pr^{2/3}$ .

#### FREE-CONVECTION BOUNDARY-LAYER SOLUTIONS

##### Brief Review of Theory

Now, attention is turned to the free-convection flow and heat transfer about an isothermal vertical plate. Two physical situations that come within the scope of the theory are shown in the following sketches:

Gravity  
↓

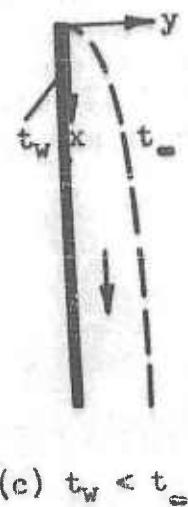

Diagram (b) depicts the case in which the wall temperature exceeds ambient. For this situation, the buoyancy forces are upward, resulting in an upflow of fluid in the boundary layer. In diagram (c), the wall is cooler than ambient and the boundary-layer flow is downward. If the coordinates are taken as shown in the sketch, there will be no need to make any particular distinction between these two situations.

The free-convection flow and heat transfer are governed by the basic conservation principles. The boundary-layer form of these laws as given by equations (1) to (3) still applies, except that a buoyancy force

$$\pm g\beta(t - t_{\infty}) \quad (24)$$

is added to the right side of the momentum equation (2). The plus sign is associated with sketch (b), while the minus sign is used with sketch (c). The appearance of a temperature term in the velocity equation means that it is no longer possible to solve for the velocity independently of the temperature; instead, simultaneous solution is necessary. In this regard, the free-convection problem becomes more complex than the forced-convection problem.

In addition to the governing equations, it is necessary to give the boundary conditions in order to complete the statement of the problem. They are

$$\left. \begin{array}{l} u = 0 \\ v = 0 \\ t = t_w \end{array} \right\} y = 0 \quad \left. \begin{array}{l} u \rightarrow 0 \\ t \rightarrow t_{\infty} \end{array} \right\} y \rightarrow \infty \quad (25)$$

where  $t_w$  is a constant

The free-convection boundary layer on an isothermal vertical plate was first solved by Schmidt and Beckmann. The conservation of mass equation (1) was satisfied by the usual stream function  $\psi$  as given by equation (5). Then, turning to momentum and energy conservation, new independent and dependent variables were introduced as follows:

$$\zeta = \frac{y}{x} \left( \frac{g\beta |t_w - t_{\infty}| x^3}{4v^2} \right)^{1/4} \quad (26a)$$

$$f(\zeta) = \frac{\psi}{(64g\beta |t_w - t_{\infty}| x^3)^{1/4}}, \quad \theta(\zeta) = \frac{t - t_{\infty}}{t_w - t_{\infty}} \quad (26b)$$

where  $\zeta$  is called a similarity variable, while  $\theta$  is a dimensionless temperature and  $f$  is related to the velocities of the problem. The absolute magnitude signs have been introduced to make the results applicable to both  $t_w > t_\infty$  and  $t_w < t_\infty$ . Under the transformation defined by equations (26a) and (26b), conservation of momentum and energy is reduced to the following pair of ordinary differential equations:

$$f''' + 3ff'' - 2(f')^2 + \theta = 0 \quad (27a)$$

$$\theta'' + 3(\text{Pr})f\theta' = 0 \quad (27b)$$

while the boundary conditions (25) become

$$\begin{aligned} f &= 0 \\ f' &= 0 \\ \theta &= 1 \end{aligned} \left. \begin{aligned} f' &\rightarrow 0 \\ \theta &\rightarrow 0 \end{aligned} \right\} \zeta \rightarrow \infty \quad (27c)$$

The primes denote differentiation with respect to  $\zeta$ , and  $\text{Pr}$  represents the Prandtl number. Since  $f$  and  $\theta$  appear in both equations, simultaneous solution is required.

Previous investigators have concentrated mainly on the range  $\text{Pr} \geq 0.7$ ; the existing solutions for low Prandtl number have already been mentioned in the INTRODUCTION.

#### Solutions and Results

Solutions. - Numerical solutions of equations (27a) and (27b) have been carried out for Prandtl numbers of 0.03, 0.02, 0.008, and 0.003 on an IBM 650 digital computer. The numerical scheme previously described for the forced-convection problem must now be modified to include simultaneous equations. Instead of looking for a single quantity  $\theta'(0)$  as before, a pair of quantities  $(\theta'(0), f''(0))$  must now be found that leads to solutions of equations (27a) and (27b) satisfying the conditions  $\theta \rightarrow 0$  and  $f' \rightarrow 0$  as  $\zeta \rightarrow \infty$ .

The values of  $\theta'(0)$  and  $f''(0)$  for which solutions were obtained are listed in table V:

TABLE V. - FREE-CONVECTION TEMPERATURE  
AND VELOCITY DERIVATIVES

| Pr   | $-\theta'(0)$ | $f''(0)$ |
|------|---------------|----------|
| 0.03 | 0.13464       | 0.93841  |
| .02  | .11164        | .95896   |
| .008 | .072464       | .99550   |
| .003 | .045139       | 1.0223   |

These quantities are not only of importance in the execution of any forward integration procedure, but they are also related to the heat-transfer and shear-stress characteristics of the flow. Hence, they are of direct practical utility.

A detailed listing of the solutions of equations (27a) and (27b) is given in table VI (see pp. 31 to 37). For each of the four Prandtl numbers considered, the dependent variables  $\theta$ ,  $\theta'$ ,  $f$ ,  $f'$ , and  $f''$  are tabulated as functions of the independent variable  $\zeta$ . These listings should provide useful information in future studies of low Prandtl number boundary layers.

Temperature and velocity profiles. - The distribution of temperature and velocity across the boundary layer is plotted in figures 3(a) to (d), each graph corresponding to a specific Prandtl number. The velocity profiles have their characteristic free-convection shape, rising rapidly to a maximum near the wall and then subsiding relatively slowly to zero with increasing values of  $\zeta$ . All velocity profiles contain an inflection point just beyond the maximum. The temperature profiles have their usual simple shape, always concave upward.

Two features of this set of graphs are worth noting. The first is that, with decreasing Prandtl number, the region of high velocity gradients occupies a relatively smaller and smaller portion of the thermal boundary layer. This suggests that, as the Prandtl number approaches zero, the effects of viscosity on the heat transfer will steadily diminish and become negligible. In the limit, the heat transfer would be expected to approach that of an inviscid fluid. The second has to do with the apparent increase of the boundary-layer thickness with decreasing Prandtl number. That this trend may not be real is easily realized by observing that fluid properties appear in the abscissa variable  $\zeta$ . With changing Prandtl number, these fluid properties will change, tending to affect the actual physical dimensions of the boundary layer.

Heat-transfer results. - For free convection, the heat transfer is the quantity of prime practical interest. The local heat-transfer

rate  $q$  is again computed from Fourier's law (eq. (12)). Introducing the dimensionless variables of equations (26a) and (26b), the expression for  $q$  becomes

$$q = -k(t_w - t_\infty) \left( \frac{g\beta |t_w - t_\infty|}{4xv^2} \right)^{1/4} \theta'(0) \quad (28)$$

A rephrasing of equation (28) in terms of dimensionless variables leads to

$$\frac{Nu_x}{Gr_x^{1/4}} = \frac{-\theta'(0)}{\sqrt{2}} \quad (29)$$

where  $Nu_x$  is the Nusselt number as previously defined and  $Gr_x$  is the Grashof number. Since the values of  $-\theta'(0)$  depend upon the Prandtl number, so will the Nusselt-Grashof relation.

The Prandtl number dependence of the dimensionless heat-transfer results may be considerably reduced by rewriting equation (29) as

$$\frac{Nu_x}{(Gr_x Pr^2)^{1/4}} = \frac{-\theta'(0)}{(2Pr)^{1/2}} \quad (30)$$

Such a step is suggested by the fact that  $Nu_x/(Gr_x Pr^2)^{1/4}$  is a constant for the inviscid free-convection flow. Numerical values of this heat-transfer parameter for low Prandtl number boundary-layer flows are given in table VII, along with the limiting inviscid result (ref. 12):

TABLE VII. - FREE-CONVECTION

HEAT-TRANSFER RESULTS

| Pr                      | $\frac{Nu_x}{(Gr_x Pr^2)^{1/4}}$ |
|-------------------------|----------------------------------|
| 0.03                    | 0.5497                           |
| .02                     | .5582                            |
| .008                    | .5729                            |
| .003                    | .5827                            |
| Pr $\rightarrow \infty$ | 0.6004                           |
| Inviscid                |                                  |

Inspection of this table shows that the group  $Nu_x/(Gr_x Pr^2)^{1/4}$  possesses the desired characteristic of being almost independent of the Prandtl number, the variation over the entire liquid-metal range being about 6 percent. It is also seen that the boundary-layer heat-transfer results smoothly approach the inviscid-flow result as the Prandtl number decreases. The information appearing in table VII is also plotted in figure 4.

For engineering purposes, a simple and very adequate representation of these results is

$$Nu_x = 0.565(Gr_x Pr^2)^{1/4} \quad (31)$$

The maximum deviation of this expression from the entries of table VII is 3 percent.

Aside from the local values, the over-all heat transfer  $Q$  from the entire surface may be of interest. An expression for the over-all heat transfer may be found by integrating equation (28) in accordance with (15). The result of integration may be put into the following dimensionless forms:

$$\frac{Nu_L}{(Gr_L)^{1/4}} = \left(\frac{4}{3}\right) \frac{-\theta'(0)}{\sqrt{2}} \quad (32a)$$

or

$$\frac{Nu_x}{(Gr_L Pr^2)^{1/4}} = \left(\frac{4}{3}\right) \frac{-\theta'(0)}{(2Pr)^{1/2}} \quad (32b)$$

The right side of equation (32b) may be immediately evaluated by multiplying the entries of table VII by  $4/3$ .

Friction-factor results. - The friction force exerted on the wall by the free-convection flow may be computed by the Newtonian shear law,

$$\tau = \mu \left( \frac{\partial u}{\partial y} \right)_{y=0} \quad (33)$$

In terms of the variables of the analysis, equation (33) may be evaluated as

$$\tau = 4\mu v x^{1/4} \left( \frac{g\beta |t_w - t_\infty|}{4v^2} \right)^{3/4} f''(0) \quad (33a)$$

In constructing a dimensionless form of equation (33a), the usual friction factor cannot be used because there is no characteristic velocity in a free-convection flow. An alternative friction factor that is sometimes used in free convection is as follows.

$$c_f^* = \frac{\tau}{\rho \left(\frac{v}{x}\right)^2} \quad (34)$$

where  $(v/x)$  plays the role of a velocity. With this, equation (33a) can be rephrased as

$$\frac{c_f^*}{(4Gr_x^3)^{1/4}} = f''(0) \quad (35)$$

The numerical values of  $f''(0)$ , given in table V, vary only by 8 percent over the entire Prandtl number range of liquid metals. For engineering purposes a satisfactory representation of the shear-stress results would be

$$c_f^* = 0.98(4Gr_x^3)^{1/4} \quad (35a)$$

Comparison with previous investigations. - Studies of the low Prandtl number free-convection boundary layer that were performed before the present investigation are described in the INTRODUCTION. The heat-transfer results as reported by previous analytical workers are summarized in table VIII:

TABLE VIII. - SUMMARY OF PREVIOUS ANALYTICAL  
HEAT-TRANSFER RESULTS FOR FREE CONVECTION

| Pr   | $Nu_x / (Gr_x \text{Pr}^2)^{1/4}$   | Reference<br>investigation |
|------|-------------------------------------|----------------------------|
| 0.03 | 0.544                               | 7                          |
| .03  | .555                                | 4                          |
| .01  | .574                                | 3                          |
| All  | $0.508 / (\text{Pr} + 0.952)^{1/4}$ | 5 and 6                    |

To facilitate comparison with the present results, the contents of this table are plotted in figure 4. The experimental data of reference 7 also appear in the figure.

In common with the current study, references 3 and 4 carried out numerical solutions of the boundary-layer equations. As seen from figure 4, their heat-transfer results fall slightly high relative to those of this investigation, the deviation being no more than 1 percent. Since the older work was performed on desk calculators and slower computers, such deviations are not at all unreasonable.

The approximation procedure of reference 7 also gives very good agreement with the present solution, falling only about 1 percent below at the point of comparison,  $Pr = 0.03$ . The result reported as corresponding to reference 7 is the average of three levels of approximation, the maximum spread among the three approximations being 16 percent.

The results based on the Kármán-Pohlhausen method lie from 7 to 12 percent below the exact solution. This agreement must be regarded as remarkably good when one considers the relatively broad assumptions used in carrying through the Kármán-Pohlhausen procedure for this problem.

The experimental data of reference 7 for mercury fall within the crosshatched band as shown in figure 4, the deviations from theory being confined to  $\pm 6$  percent. This very good agreement may be interpreted as a strong support of the analytical predictions.

#### CONCLUDING REMARKS

Although laminar-boundary-layer theory can supply information on heat-transfer and skin-friction characteristics, it cannot predict the region of applicability of these results. For sufficiently high Reynolds or Grashof numbers, the flow will become turbulent. On the other hand, for sufficiently low Reynolds or Grashof numbers, the boundary layer is relatively thick, and certain assumptions of the theory are no longer valid. It remains for experiment to define the limits of applicability of the theory.

For low Prandtl number forced-convection flows, transition to turbulence should occur in the same Reynolds number range ( $5 \times 10^4$  to  $10^6$ ) as for high Prandtl number fluids. On the other hand, in the absence of experiments involving liquid metals, it cannot be stated which Reynolds numbers are sufficiently low to invalidate the boundary-layer assumptions as a consequence of a too thick thermal boundary layer. All that can be stated is that the (thermal) boundary-layer assumptions will not remain valid to as low Reynolds numbers for low Prandtl number flows as they do for high Prandtl number fluids.

For free-convection flows, it is rather uncertain that information on laminar-turbulent transition for high Prandtl number fluids can be applied to low Prandtl number fluids. Therefore, at present, the extent

E-163

of the laminar regime for low Prandtl number fluids must be regarded as unknown. Further, a state of uncertainty exists as to when the boundary-layer assumptions become invalid because of a too thick boundary layer. For gases, it has been established that boundary-layer heat-transfer predictions are correct when  $Gr_x > 5 \times 10^4$ . For liquid metals, it may be conjectured that this limit will be at a higher Grashof number, but it is not known how much higher.

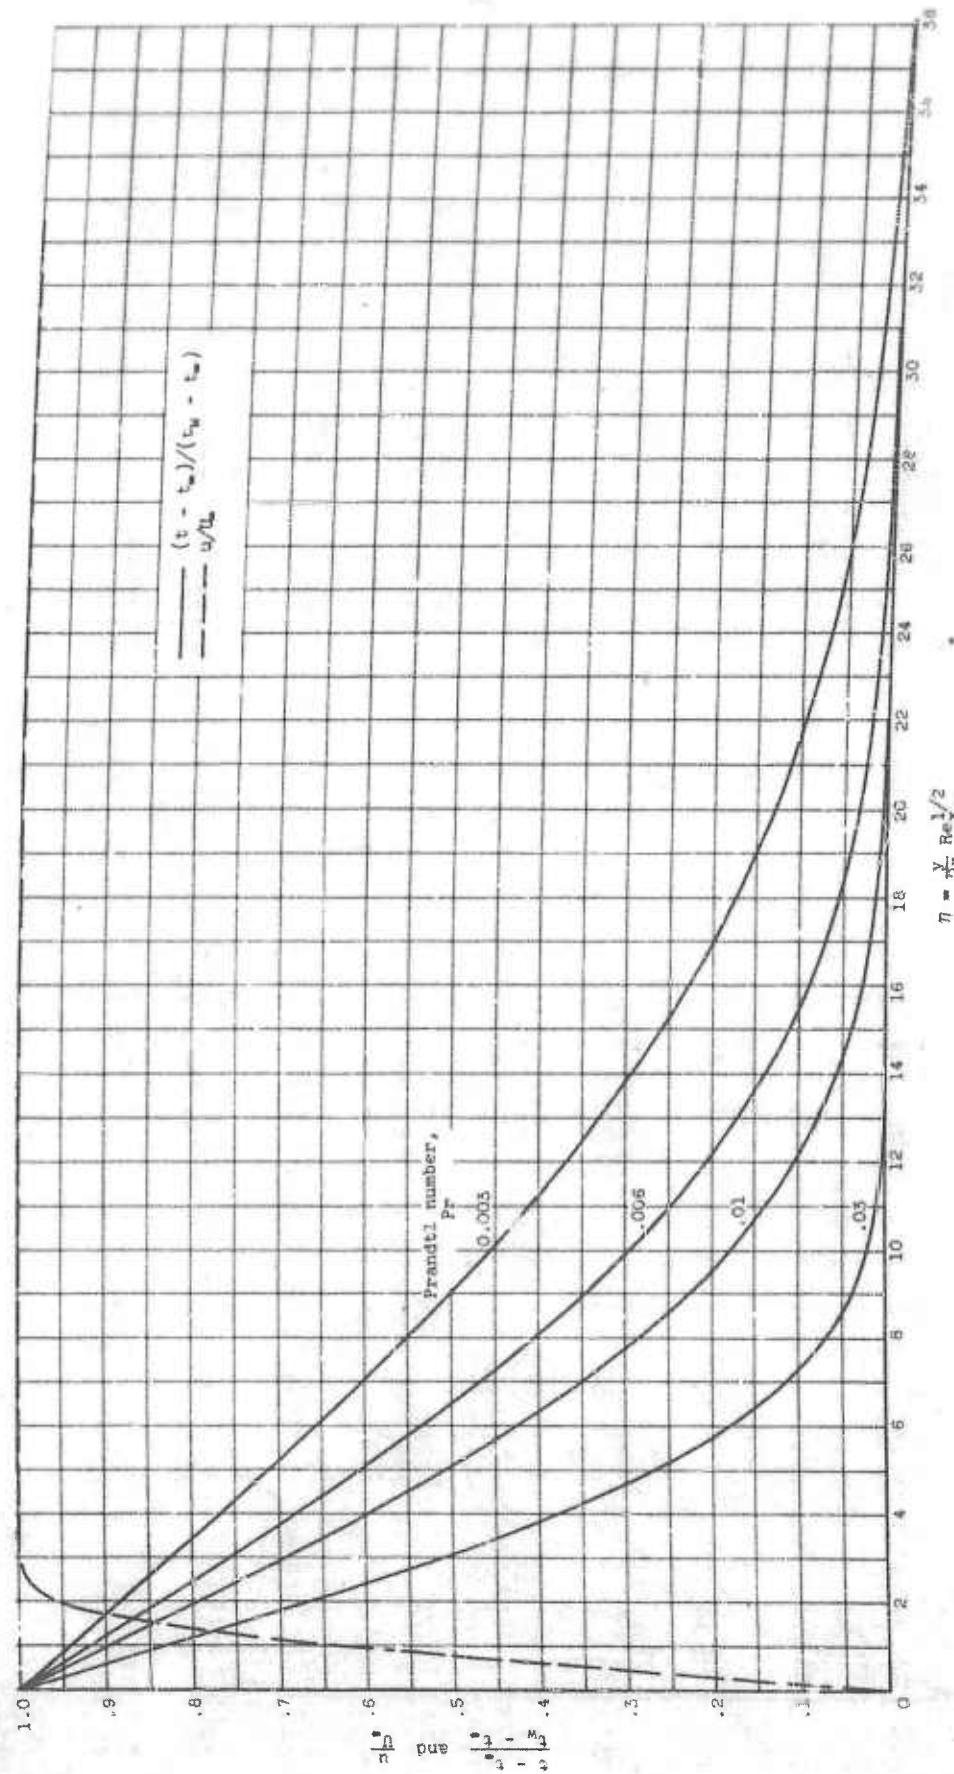

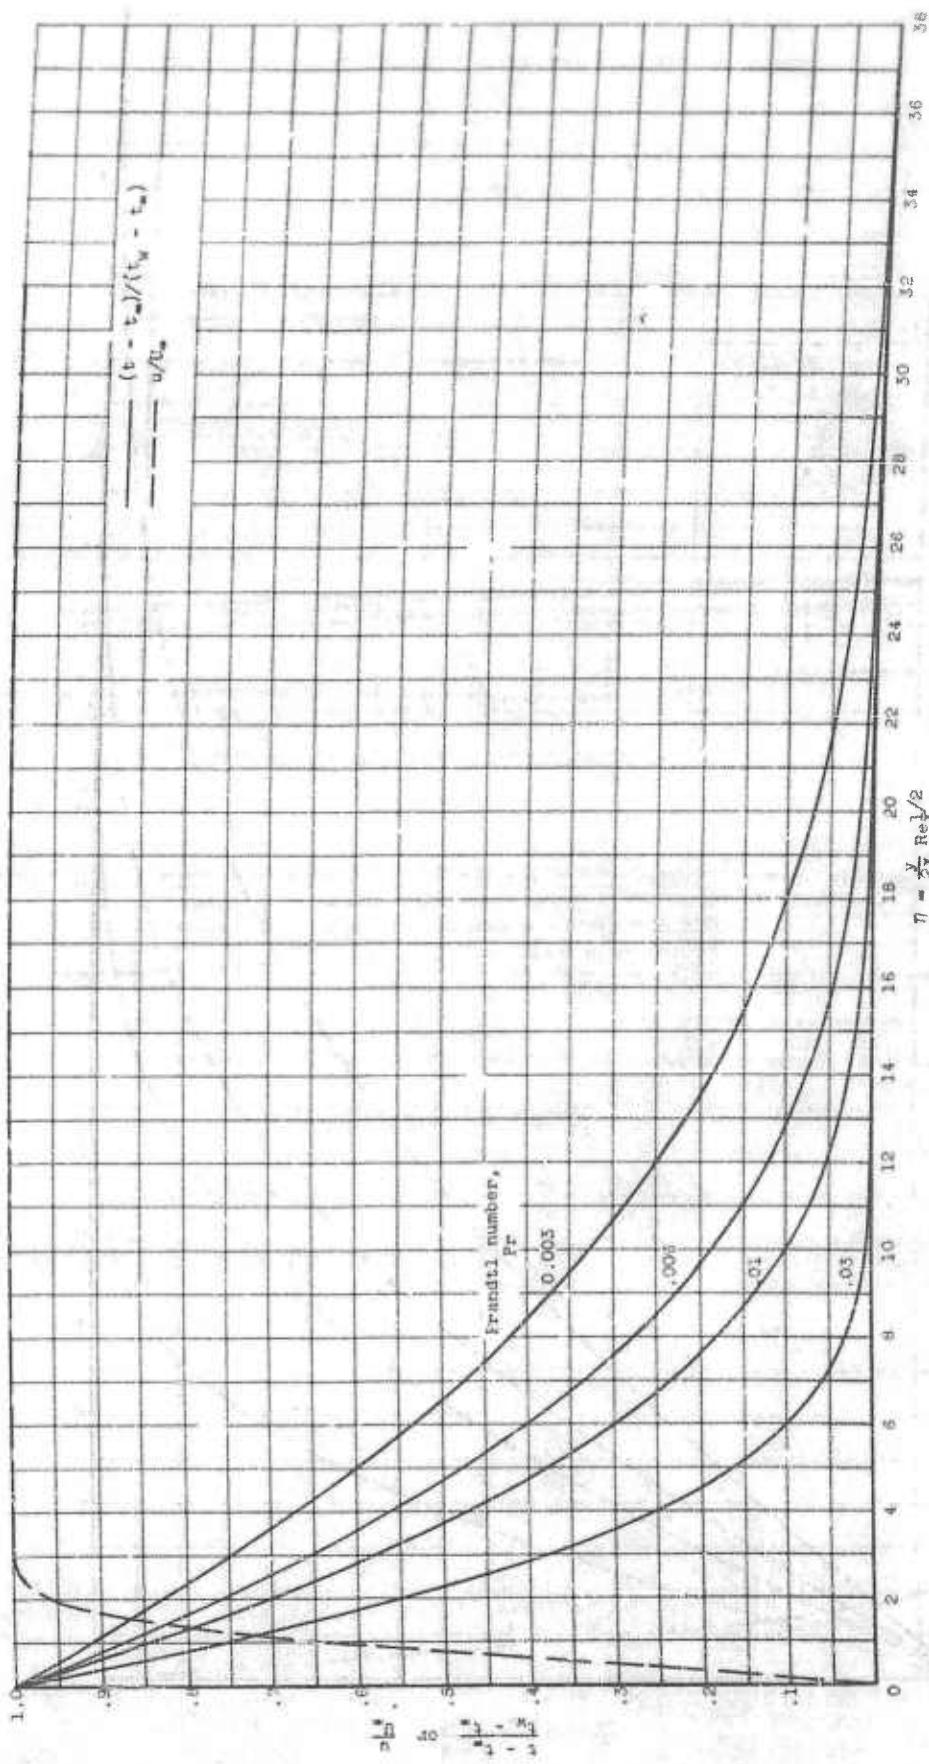

Figure 1. - Forced-convection temperature and velocity profiles.  
 (a) Uniform-wall-temperature situation.

(b) Uniform-heat-flux situation.  
Figure 1. - Concluded. Forced-convection temperature and velocity profiles.

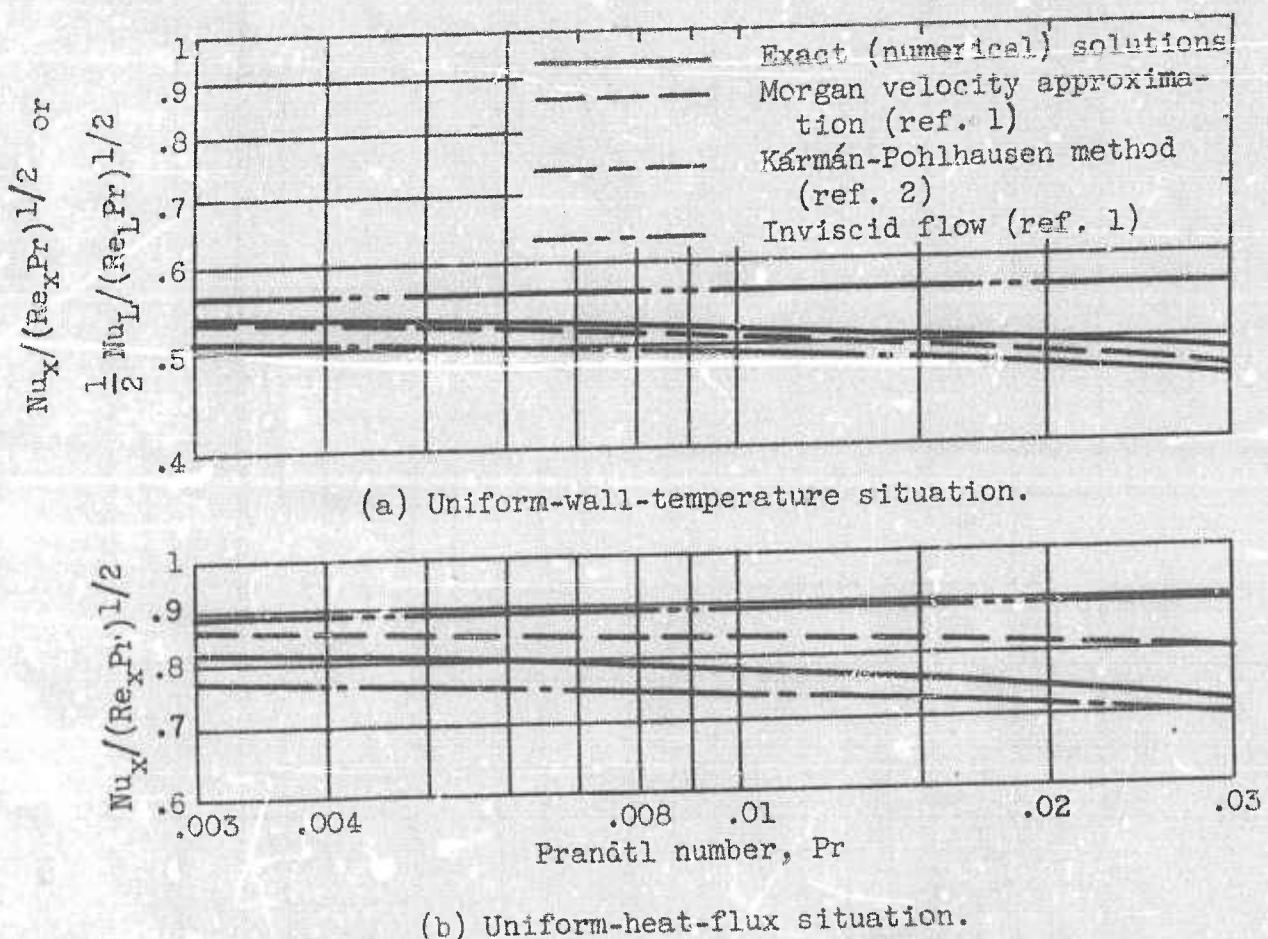

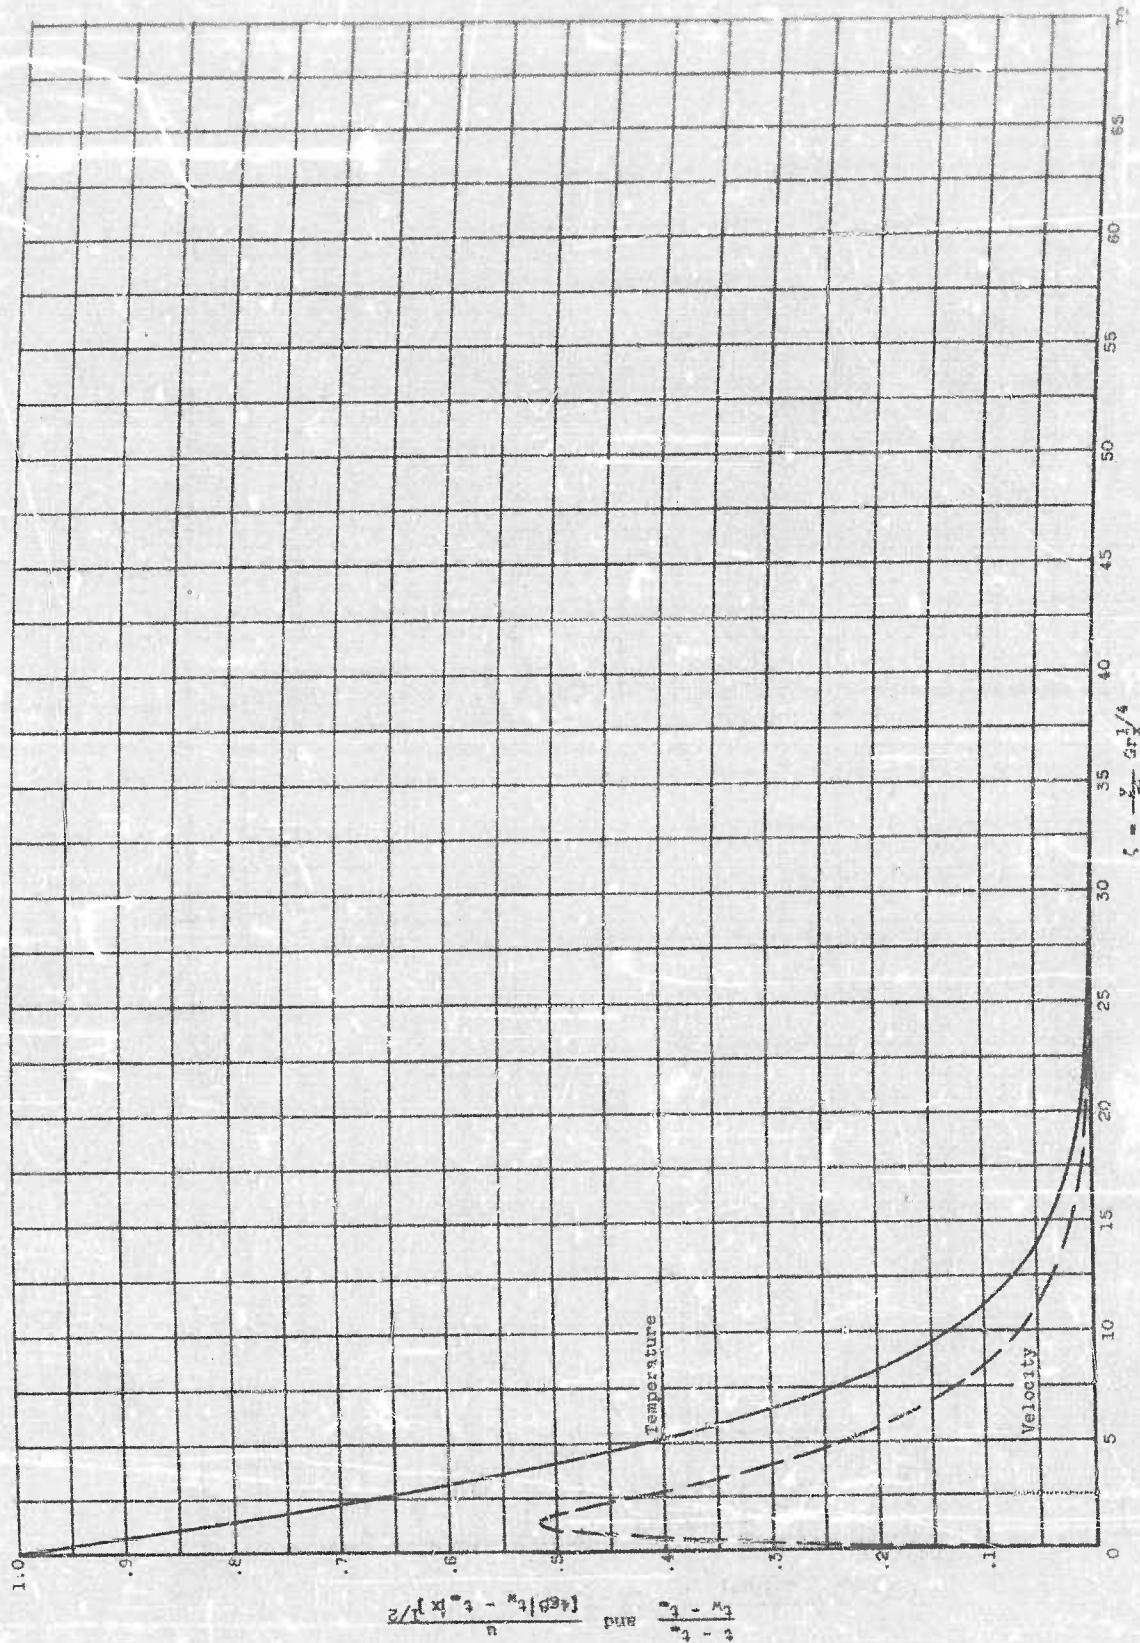

Figure 2. - Forced-convection heat-transfer characteristics.

(a) Prandtl number, 0.03.  
Figure 3. - Free-convection temperature and velocity profiles.

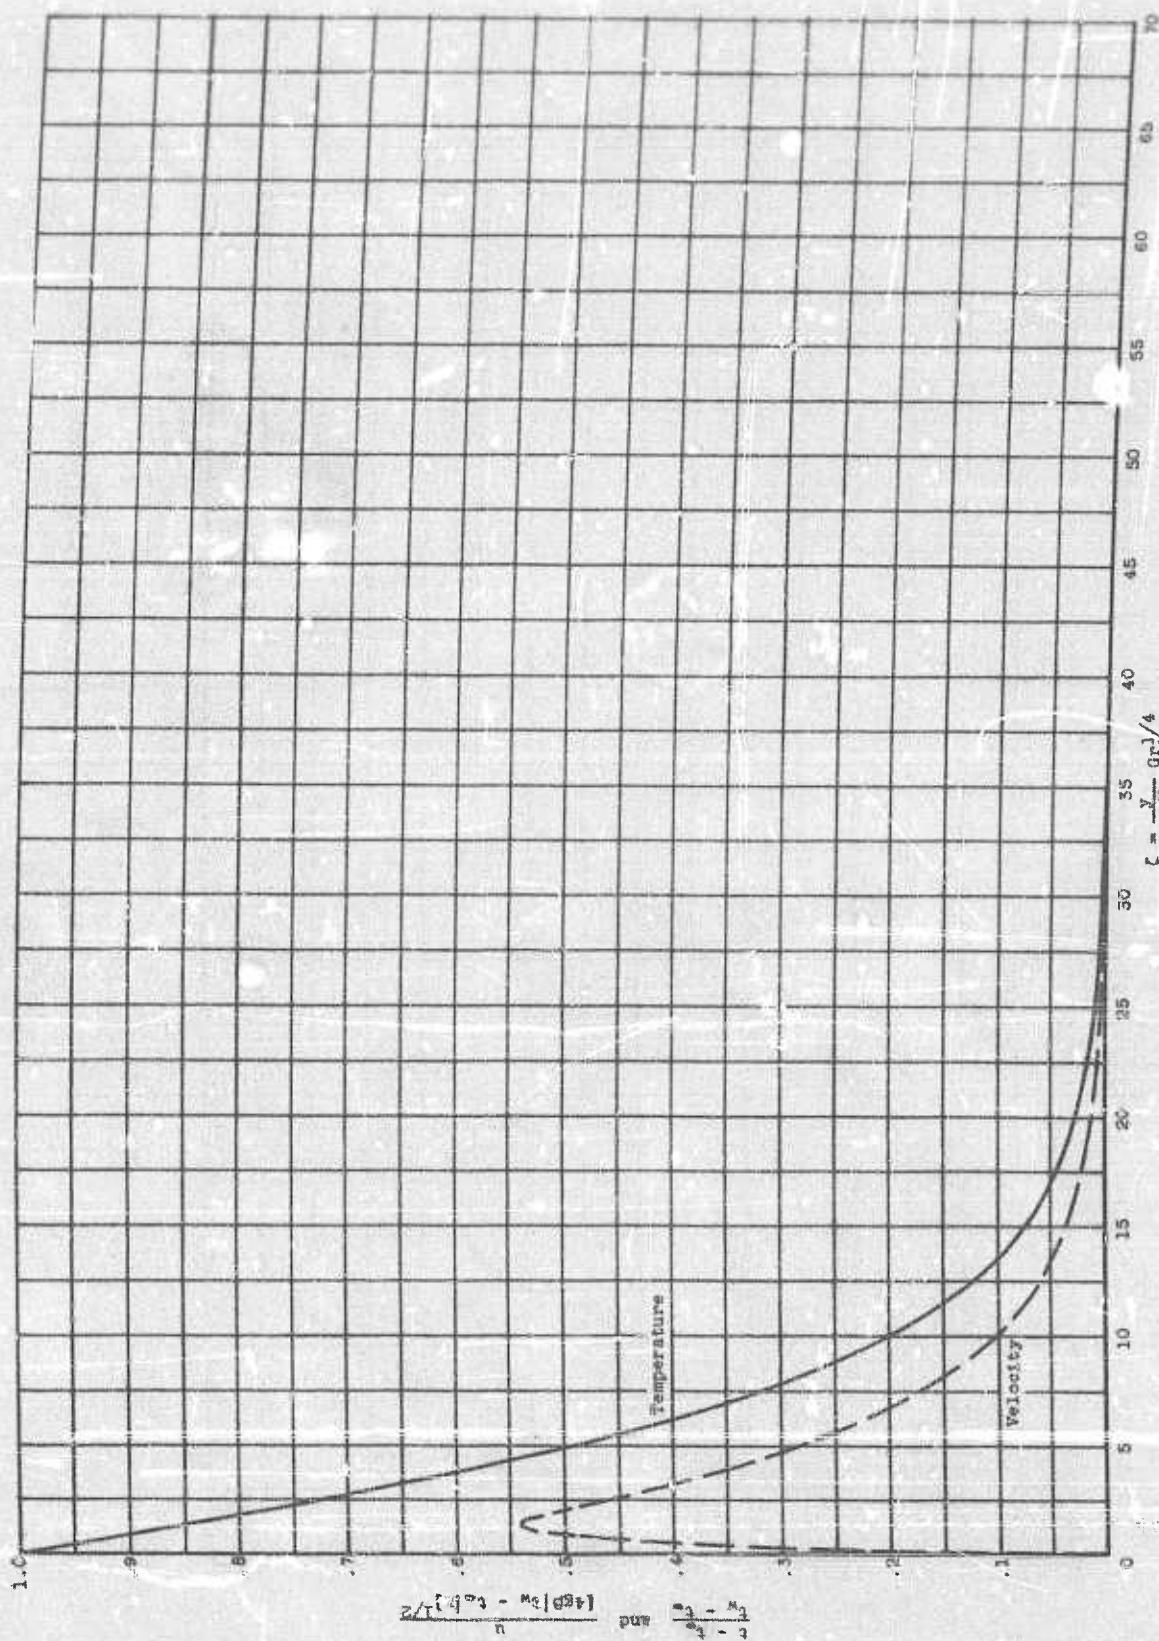

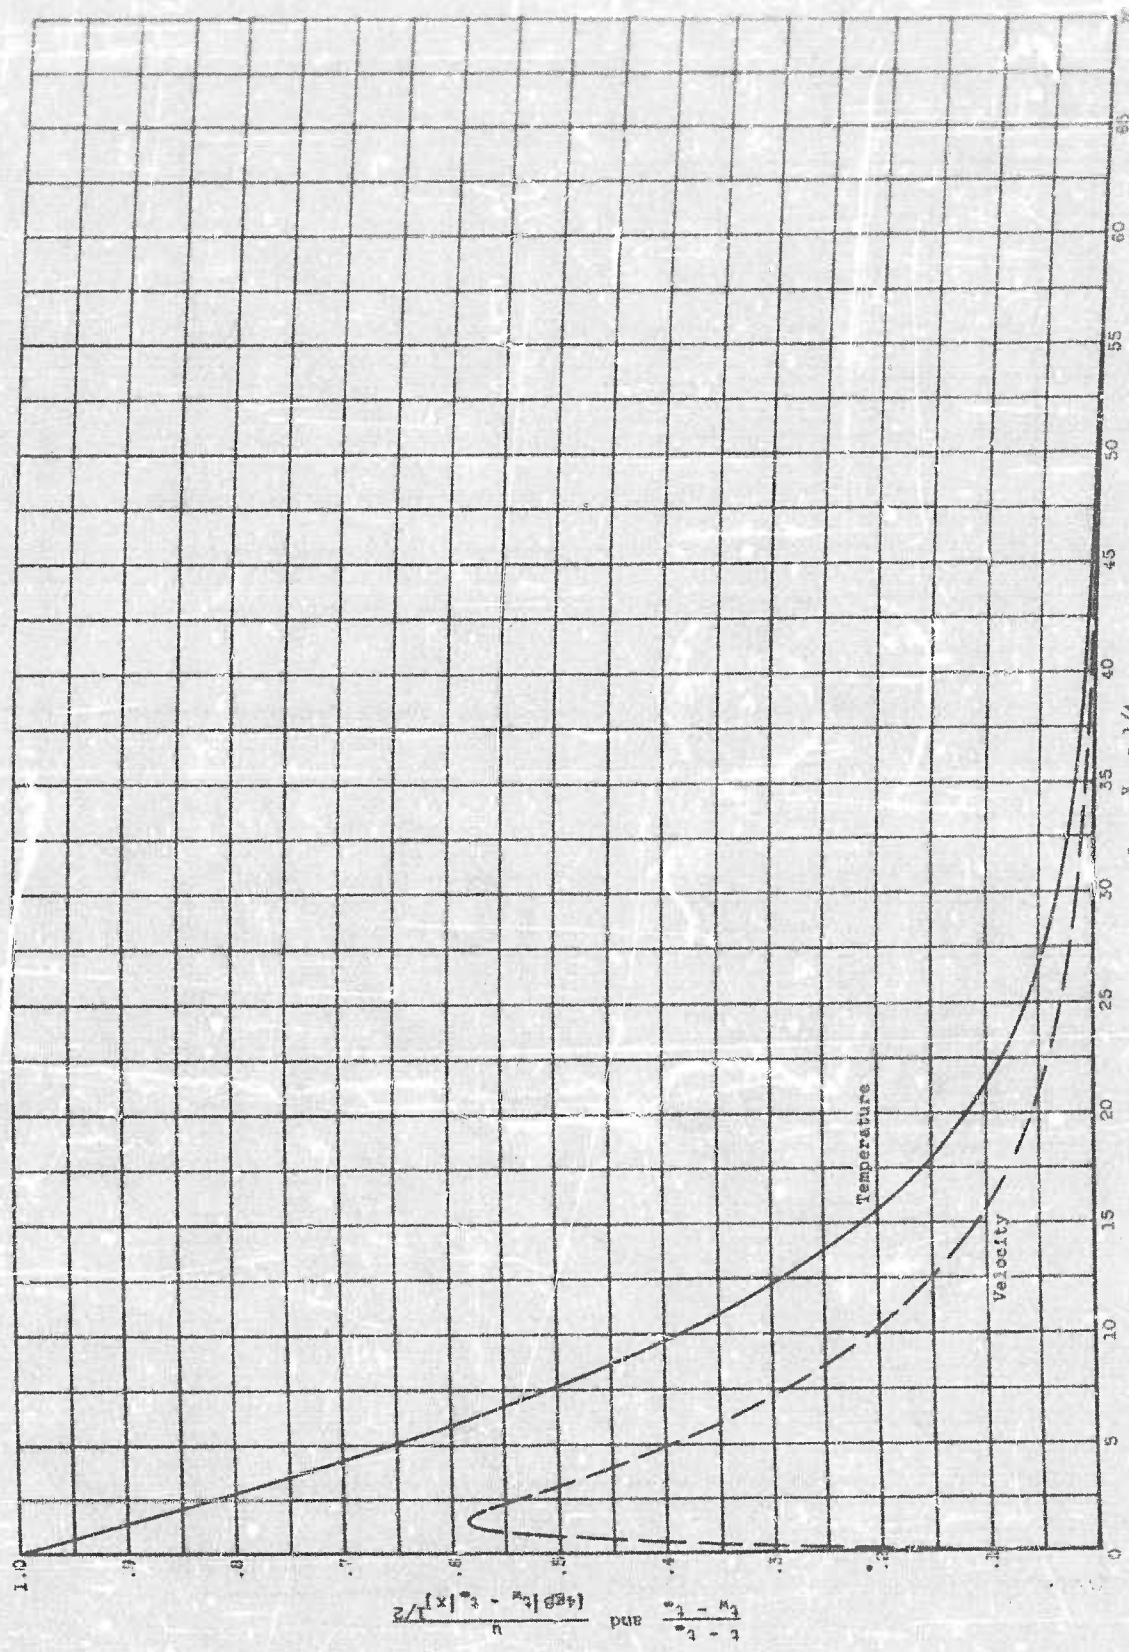

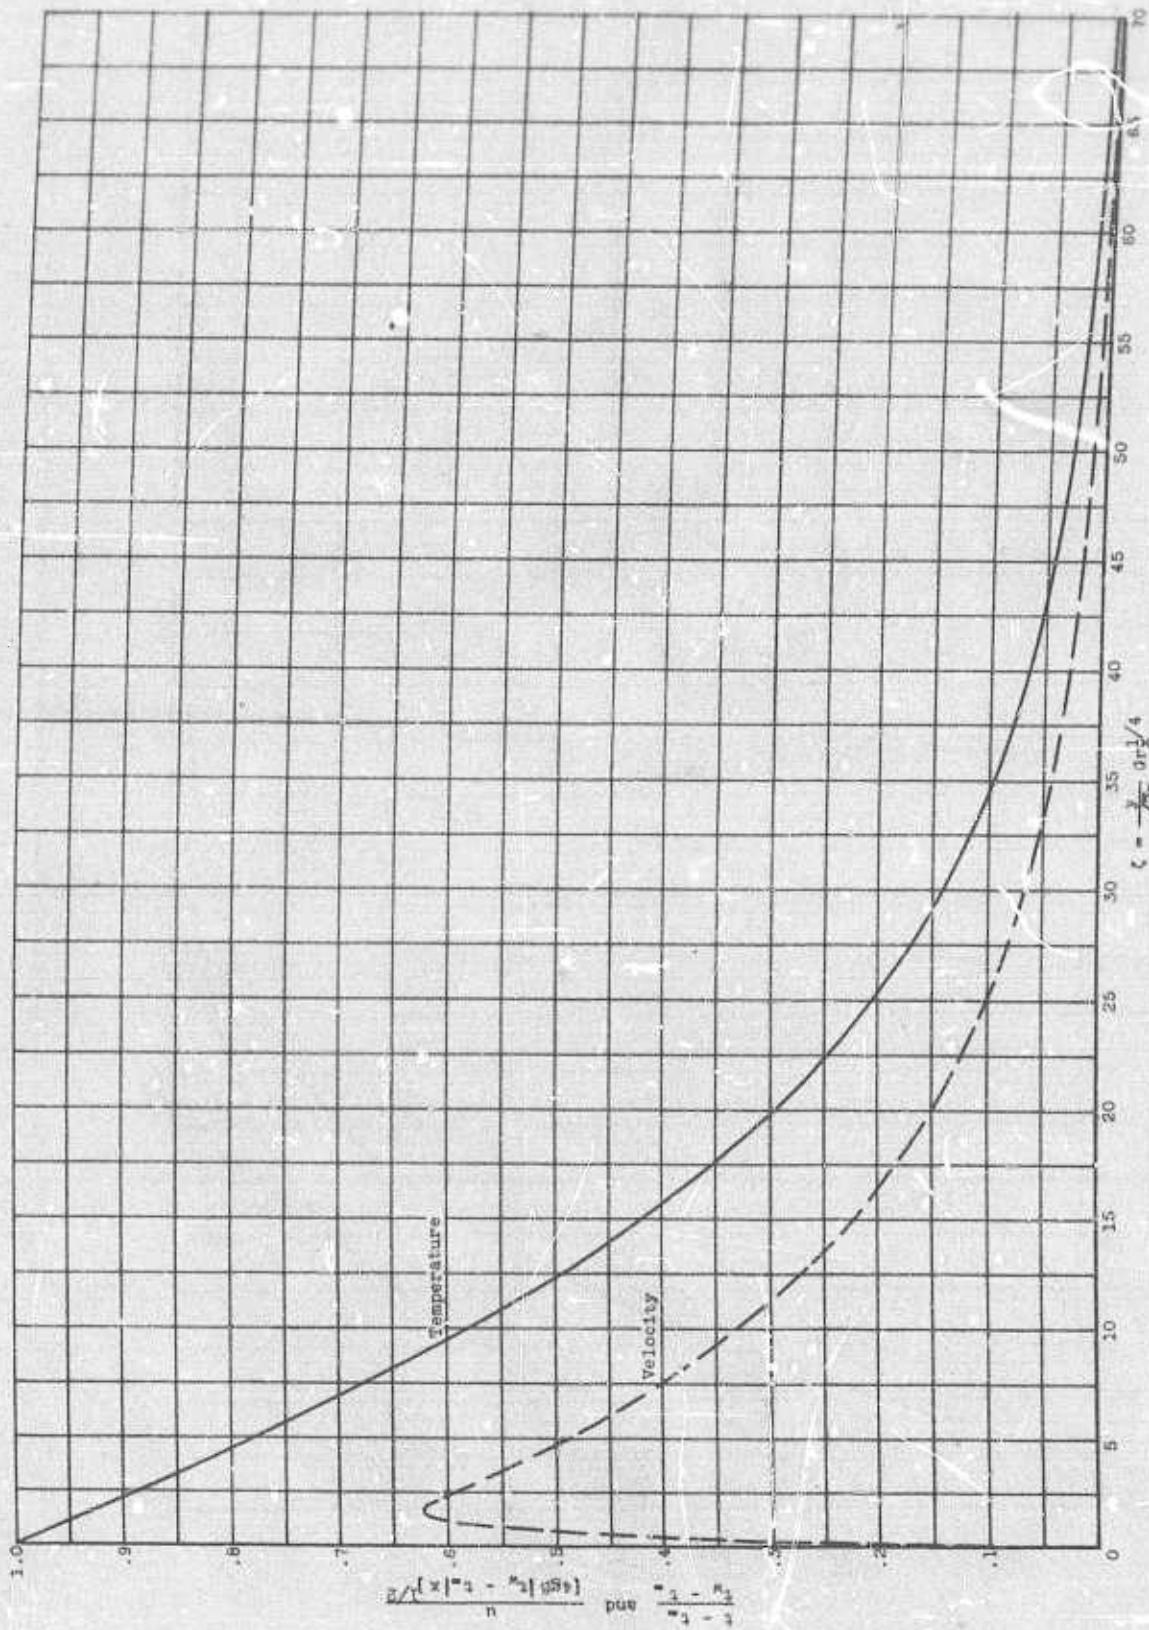

Figure 3. - Continued. Pre-convection temperature and velocity profiles.  
(b) Prandtl number, 0.02.

(c) Prandtl number, 0.008.

FIGURE 3. - Continued. Free-convection temperature and velocity profiles.

(d) Prandtl number, 0.003.

Figure 3. - Concluded. Free-convection temperature and velocity profiles.

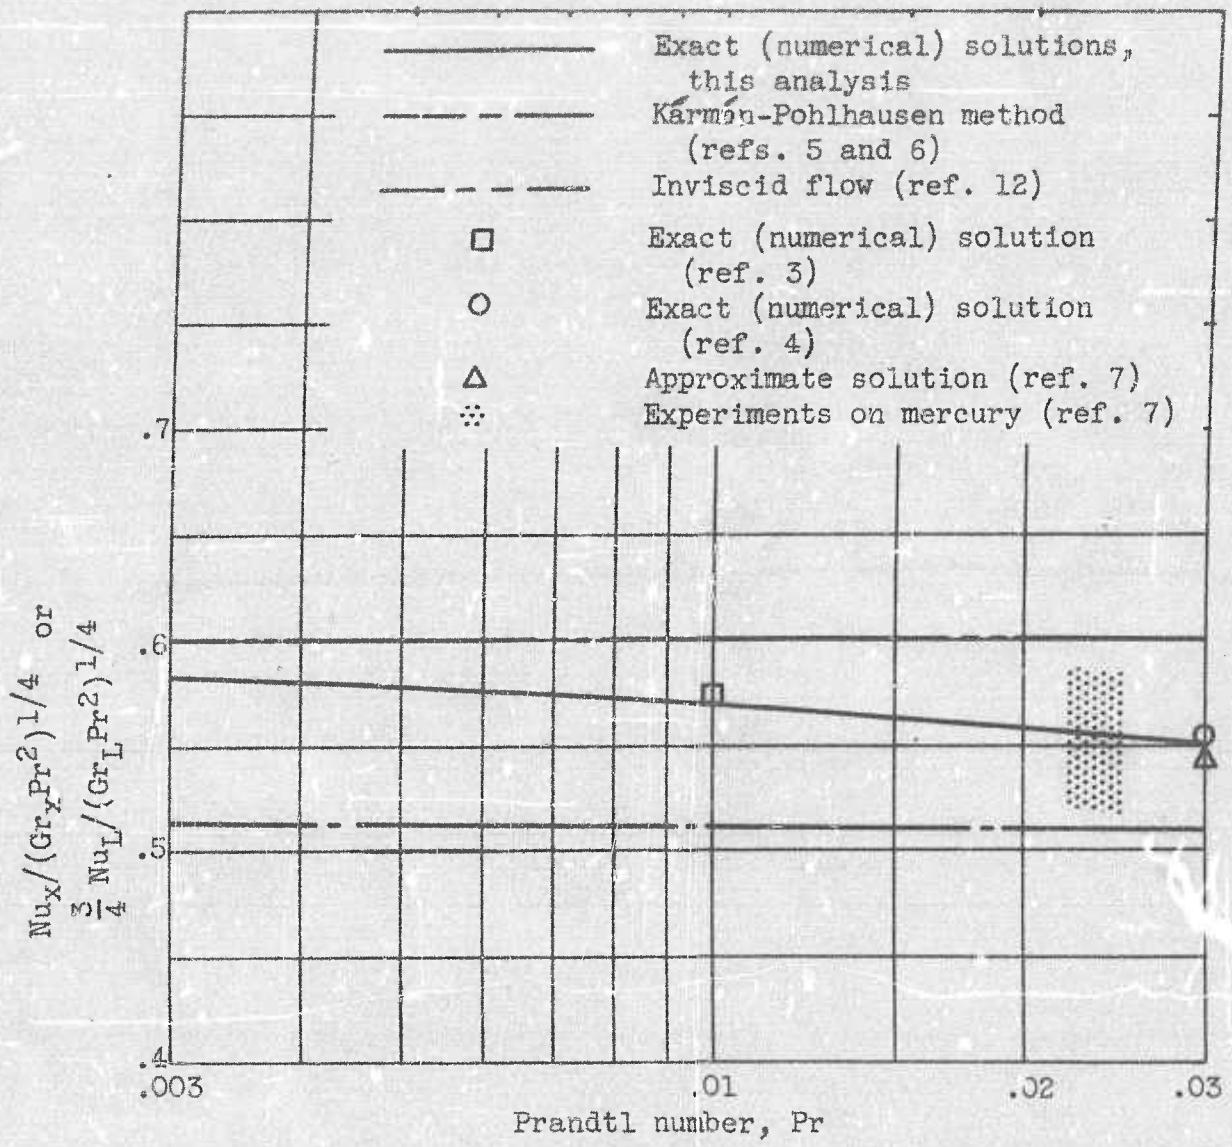

Figure 4. - Free-convection heat-transfer characteristics.
